Abstract

Nattokinase, from the Japanese fermented food natto, is a protease with fibrinolytic activity that can thus degrade conventional blood clots. In some cases, however, including in Long COVID, fibrinogen can polymerise into an anomalous amyloid form to create clots that are resistant to normal fibrinolysis and that we refer to as fibrinaloid microclots. These can be detected with the fluorogenic stain thioflavin T. We describe an automated microscopic technique for the quantification of fibrinaloid microclot formation, which also allows the kinetics of their formation and aggregation to be recorded. We also here show that recombinant nattokinase is effective at degrading the fibrinaloid microclots in vitro. Flow conditions, mimicked by shaking, increase the size of the clots via aggregation. Overall, this work adds to the otherwise largely anecdotal evidence, that we review, that nattokinase might be anticipated to have value as part of therapeutic treatments for individuals with Long COVID and related disorders that involve fibrinaloid microclots.

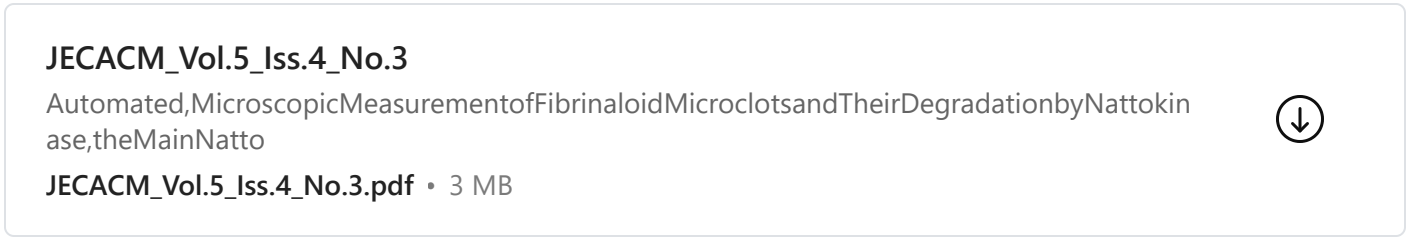
Breakthrough in-vitro study finds a natural enzyme potently degrades **the same amyloid microclots recently detected in 100% of COVID-19 vaccinated individuals tested.**



Scientists created true amyloid microclots in the lab—the same spike-induced, β-sheet structures now widely seen in Long VACCINE and Long COVID [mRNA vaccine injury] patients.

Then they exposed them to **nattokinase**:

84% reduction in total microclot count

52% drop in amyloid intensity

Rapid action within 2 hours

This is the first biochemical evidence that these pathological amyloid clots can be dissolved with a safe and natural compound.

Human studies must begin immediately.
